Natural Language Processing Report

Clustering Analysis on the 20 Newsgroups Dataset

1. Introduction

Natural Language Processing (NLP) is a subfield of artificial intelligence that focuses on enabling machines to understand, interpret, and generate human language. One of the fundamental challenges in NLP is representing unstructured text data in a form that machine learning algorithms can process effectively.

This project explores key NLP techniques including text preprocessing, feature extraction, and unsupervised learning through clustering. The primary objective is to analyze patterns in textual data and group similar documents without prior labeling.

The **20 Newsgroups dataset**, consisting of approximately 20,000 documents across 20 distinct topics, is used as the basis for this analysis. It provides a diverse and realistic corpus for evaluating text clustering techniques.

2. Dataset Description

The dataset contains text documents collected from 20 different online discussion groups (newsgroups). Each document belongs to one of the following categories:

- Technology (e.g., computers, graphics)
- Science (e.g., space, electronics)
- Politics
- Religion
- Sports
- Miscellaneous topics

Key Characteristics:

- Total documents: ~20,000
- Number of categories: 20
- Data type: Unstructured text

For computational efficiency, a subset of the dataset (2,000 documents) was used during experimentation.

3. Methodology

3.1 Text Preprocessing

Raw text data is noisy and must be cleaned before analysis. The following preprocessing steps were applied:

- **Lowercasing:** All text converted to lowercase to ensure uniformity
- **Punctuation Removal:** Eliminated special characters and symbols
- **Tokenization:** Split text into individual words

- **Stopword Removal:** Removed common words (e.g., “the”, “is”) that carry little semantic meaning

This step ensures that only meaningful words contribute to feature extraction.

3.2 Text Representation

To apply machine learning algorithms, text must be converted into numerical form. Three techniques were explored:

3.2.1 Bag of Words (BoW)

The Bag of Words model represents text as a frequency vector of words.

- Each document is converted into a vector
- Each position corresponds to a word in the vocabulary
- Values represent word counts

Advantages:

- Simple and easy to implement

Limitations:

- Ignores context and word importance
- Treats all words equally

3.2.2 TF-IDF (Term Frequency–Inverse Document Frequency)

TF-IDF improves upon BoW by assigning weights to words based on importance.

- **Term Frequency (TF):** Frequency of a word in a document
- **Inverse Document Frequency (IDF):** Reduces weight of common words across documents

Advantages:

- Highlights meaningful and distinctive words
- Reduces noise from frequent terms

3.2.3 Word Embeddings (Word2Vec)

Word embeddings map words into dense vector representations capturing semantic relationships.

- Words with similar meanings have similar vectors
- Example: "computer" and "technology" are closely related

A basic Word2Vec model was trained on the dataset.

Advantages:

- Captures semantic meaning
- Useful for advanced NLP tasks

Limitations:

- Computationally more expensive
- Not directly used for clustering in this implementation

3.3 Clustering Algorithm

K-Means Clustering

K-Means is an unsupervised learning algorithm used to group similar data points.

Process:

1. Select number of clusters (K = 20)
2. Initialize centroids randomly
3. Assign each document to the nearest centroid
4. Update centroids based on assigned points
5. Repeat until convergence

K-Means was applied to TF-IDF feature vectors.

4. Model Evaluation

4.1 Silhouette Score

The silhouette score measures how well documents fit within their assigned clusters.

- Range: **-1 to 1**
    - Close to **1** → well-clustered
    - Close to **0** → overlapping clusters
    - Negative → incorrect clustering

The obtained score indicated **moderate clustering performance**, suggesting that while clusters exist, some overlap remains.

4.2 Cluster Interpretation

Each cluster was analyzed by examining its top terms.

Example findings:

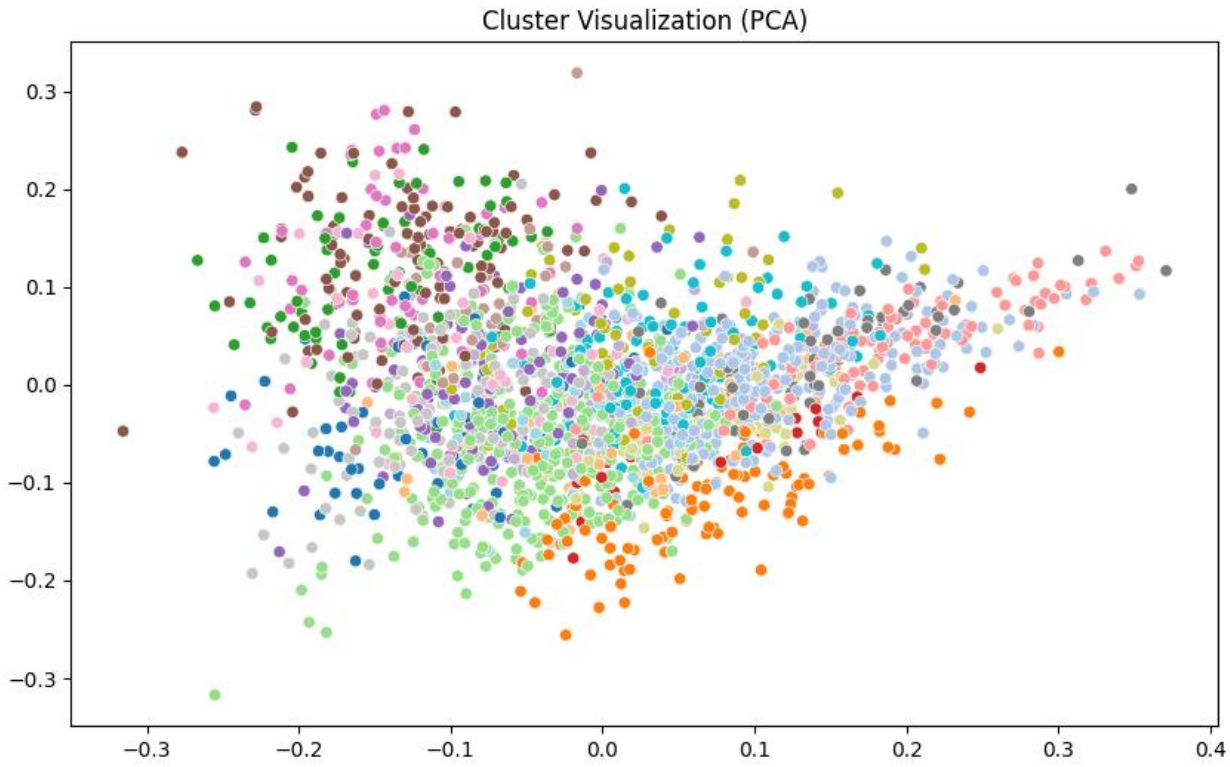
- Some clusters strongly represented **technology topics**
- Others reflected **sports or political discussions**
- A few clusters were mixed, indicating overlap in themes

5. Visualization

Dimensionality reduction using Principal Component Analysis (PCA) was applied to visualize clusters in two dimensions.

Observations:

- Some clusters formed clearly separable groups
- Others overlapped significantly
- High-dimensional text data is difficult to separate perfectly



6. Prediction on New Documents

The trained clustering model was used to assign clusters to unseen text.

Example:

Input:

"The graphics card in my computer is powerful"

Output:
→ Assigned to a cluster related to **technology/computers**

This demonstrates that the model can generalize to new inputs.

7. Results and Discussion

Key Findings:

- **TF-IDF outperformed BoW** in clustering quality
- K-Means successfully grouped similar documents

- Some clusters were highly interpretable
- Overlap between topics reduced clustering accuracy

Challenges:

- High dimensionality of text data
- Ambiguity in language (same word, different meanings)
- Similar vocabulary across different topics

8. Critical Analysis

This section provides a deeper evaluation of the methodologies used and highlights both strengths and limitations of the approach.

8.1 Effectiveness of Feature Extraction Methods

The choice of text representation significantly impacted clustering performance.

- **Bag of Words (BoW)** was simple but limited. It treated all words equally, ignoring their importance and context. This resulted in noisy clusters where common words dominated.
- **TF-IDF** provided a noticeable improvement by reducing the influence of frequently occurring words and emphasizing more informative terms. As a result, clusters became more interpretable and aligned better with real-world topics.
- **Word Embeddings** (Word2Vec) captured semantic relationships between words, which is a major advantage over BoW and TF-IDF. However, in this implementation, embeddings were not directly used for clustering, limiting their practical impact.

8.2 Limitations of K-Means Clustering

While K-Means is efficient and widely used, it has several drawbacks when applied to text data:

- **Assumption of spherical clusters:** Text data does not naturally form evenly shaped clusters
- **Fixed number of clusters (K):** Choosing K = 20 was intuitive (based on dataset categories), but not necessarily optimal
- **Sensitivity to initialization:** Different runs may produce different results
- **Difficulty with overlapping topics:** Many documents contain multiple themes

These limitations explain why some clusters overlapped or lacked clear separation.

8.3 Challenges in Text Clustering

Several inherent challenges affected the results:

- **High dimensionality:** Even with feature limits, text vectors remain large and sparse
- **Semantic ambiguity:** Words can have multiple meanings depending on context
- **Shared vocabulary:** Different topics often use similar words, making separation difficult

8.4 Evaluation Constraints

The **silhouette score** provided a useful quantitative measure, but it has limitations:

- It does not fully capture semantic correctness
- A high score does not always mean meaningful topic grouping
- Human interpretation is still necessary for validating clusters

8.5 Overall Assessment

Despite limitations, the approach successfully demonstrated:

- The importance of preprocessing
- The superiority of TF-IDF over basic frequency methods
- The feasibility of unsupervised learning in discovering hidden structures in text

However, more advanced techniques could significantly improve performance.

8.6 Recommendations for Improvement

Future work could include:

- Using **Hierarchical Clustering** for better structure discovery
- Applying **dimensionality reduction techniques** like t-SNE or UMAP
- Leveraging **advanced embeddings** (e.g., transformer-based models)
- Automatically determining optimal cluster numbers (e.g., Elbow Method)

9. Comparison of Text Representation Techniques

9.1 Summary Table

Feature	Bag of Words (BoW)	TF-IDF	Word Embeddings (Word2Vec)
Representation Type	Sparse vector	Weighted sparse vector	Dense vector
Captures Word Frequency	Yes	Yes	No (implicit)
Captures Word Importance	No	Yes	Yes
Captures Context/Semantics	No	Limited	Strong
Dimensionality	High	High	Low (fixed size vectors)
Interpretability	High	Medium	Low
Computational Cost	Low	Moderate	High
Performance in Clustering	Poor	Good	Moderate (not directly applied)

9.2 Detailed Comparison

Bag of Words

- Works well for simple tasks
- Fails to capture meaning or relationships
- Produces sparse and high-dimensional data

TF-IDF

- Improves BoW by weighting important words
- Reduces noise from frequent but irrelevant terms
- Still lacks deep semantic understanding

Word Embeddings

- Captures relationships between words (semantic similarity)
- More suitable for advanced NLP tasks
- Requires more computation and tuning
- Less interpretable compared to BoW/TF-IDF

9.3 Final Insight

For this assignment:

- **TF-IDF is the most effective choice** for clustering
- **BoW is too simplistic** for meaningful grouping
- **Word embeddings are powerful**, but require more advanced implementation to fully utilize

10. Conclusion

This project demonstrated the application of NLP techniques for unsupervised text clustering.

Summary:

- Text preprocessing significantly improves data quality
- TF-IDF is an effective feature extraction method
- K-Means clustering can identify underlying topics
- Evaluation metrics like silhouette score are essential
- TF-IDF offered the best balance between simplicity and performance for clustering tasks in this project.

Future Improvements:

- Use **Hierarchical Clustering** for better structure
- Apply **advanced embeddings (BERT, GloVe)**

- Increase dataset size for better generalization
- Optimize number of clusters dynamically

11. Final Insight

- **TF-IDF is the most effective choice** for clustering
- **BoW is too simplistic** for meaningful grouping
- **Word embeddings are powerful**, but require more advanced implementation to fully utilize
